Just Accepted

“Just Accepted” manuscripts have been peer-reviewed and accepted for publication. They are posted online prior to technical editing, formatting for publication and author proofing. The American Chemical Society provides “Just Accepted” as a free service to the research community to expedite the dissemination of scientific material as soon as possible after acceptance. “Just Accepted” manuscripts appear in full in PDF format accompanied by an HTML abstract. “Just Accepted” manuscripts have been fully peer reviewed, but should not be considered the official version of record. They are accessible to all readers and citable by the Digital Object Identifier (DOI®). “Just Accepted” is an optional service offered to authors. Therefore, the “Just Accepted” Web site may not include all articles that will be published in the journal. After a manuscript is technically edited and formatted, it will be removed from the “Just Accepted” Web site and published as an ASAP article. Note that technical editing may introduce minor changes to the manuscript text and/or graphics which could affect content, and all legal disclaimers and ethical guidelines that apply to the journal pertain. ACS cannot be held responsible for errors or consequences arising from the use of information contained in these “Just Accepted” manuscripts.

Identification of Receptor Binding to the Biomolecular Corona of Nanoparticles

3 ABSTRACT
4
5
6

7 Biomolecules adsorbed on nanoparticles are known to confer a biological identity to
8 nanoparticles, mediating the interactions with cells and biological barriers. However, how these
9 molecules are presented on the particle surface in biological milieu remains unclear. The central
10 aim of this study is to identify key protein recognition motifs and link them to specific cell-
11 receptor interactions. Here we employed an immuno-mapping technique to quantify epitope
12 presentations of two major proteins in the serum corona, low-density lipoprotein and
13 immunoglobulin G. Combining with a purpose-built receptor expression system, we show that
14 both proteins present functional motifs to allow simultaneous recognition by low-density
15 lipoprotein receptor and Fc-gamma receptor I of the corona. Our results suggest that the
16 ‘labelling’ of nanoparticles by biomolecular adsorption processes allows for multiple pathways
17 in biological processes in which they may be ‘mistaken’ for endogenous objects, such as
18 lipoproteins, and exogenous ones, such as viral infections.

3 When the nanoparticle (NP) surface comes in contact with a biological milieu, adsorption
4 processes lead to a surface-assembly of biomolecules derived from the environment, which has
5 been termed ‘biomolecular corona’.¹⁻³ It is now widely acknowledged that sufficiently long-lived
6 (‘hard corona’) biomolecular motifs presented at the surface would define how a NP first
7 interacts with and is recognised by cells,⁴⁻¹¹ and such interactions likely define many key
8 biological outcomes (*e.g.*, bio-distribution, targeting, and immune responses).¹²⁻²⁵ For example,
9 apolipoproteins and immunoglobulins have been identified in the biomolecular corona of various
10 types of NPs.³ Their presence has been suggested to promote active processes driven by
11 receptors on the cells of the liver, which leads to liver accumulation of NPs that have commonly
12 observed for many types of NPs.²⁶ However, so far the identities of the proteins that were tightly
13 bound to an ensemble of NPs have been determined by mass spectrometry analysis of all the
14 proteins extracted from the surface of all the NPs,^{3,27} which provides little information on how
15 these proteins are organised and their binding motifs are presented. The lack of molecular details
16 of corona conformation has hindered us to meaningfully determine ‘what the cell sees’.^{28,29} Now
17 approaches using immuno-probes for detection of specific protein epitopes presented outwards
18 on the NP surface have recently been developed.^{30,31} These allow us to seek direct microscopic
19 molecular connections between the biomolecular corona and specific receptors.

20
21 Here we present a systematic method to advance such hypotheses by direct investigation of
22 NP-receptor interactions in biological milieu. As one example, a protein corona derived from
23 human serum on 100 nm silica (SiO₂) NPs was chosen as a model. Given the abundance of low-
24 density lipoprotein (LDL) and immunoglobulin G (IgG) in the corona characterised by
25 proteomics analysis, their orientation on the corona was probed by mapping the epitopes of
26 apolipoprotein B-100 (ApoB-100) epitope for LDL and Fc region for IgG. Approximately 60

3 ApoB-100 binding sites and 180 Fc binding sites per particle were detected in the biomolecular
4 corona derived from 50% human serum by using fluorescence reporter binder (quantum dots
5 (QDs) functionalized with antibodies). Subsequently, we developed a receptor-fusion protein
6 expression system to study specific recognition by LDL receptor (LDLR) and Fc-gamma
7 receptor I (Fc γ RI) in appropriate biological milieu. We recognize the difficulty of maintaining
8 effective receptor interactions with soluble receptor fragments for most receptors of interest.
9 Thus, the purpose of these receptor fusion systems is to host relevant receptors, in a manner that
10 retains binding capacity, without seeking to re-engineer the host cell, and all of the complexity
11 and uncertainty this entails. As such the readout of specific recognition of biomolecular corona
12 by receptors is an increase of NP uptake when cells express the receptors in comparison to being
13 devoid of the receptors. The presence of free proteins in normal serum is likely to decrease the
14 detection window, as the competition between free proteins and NP-adsorbed protein recognition
15 motifs for specific membrane receptors would only occur in receptor-expressing cells. Therefore,
16 NP uptake was carried out in human serum that was depleted from the free proteins that are
17 binding ligands for a given receptor in this study. Our data have shown that the uptake of NPs is
18 significantly increased in the cells with greatly elevated expression of either LDLR or Fc γ RI,
19 suggesting that the specific recognition of corona by the both receptors is coexistent. The
20 specificity of the receptor recognition was further confirmed by competition binding of free
21 ligands with increasing concentrations. Taken together, this study has illustrated that
22 biomolecular corona of NPs retain multiple binding motifs, which can be specifically recognised
23 by different receptors potentially with diverse receptor-ligand affinity.

55 RESULTS AND DISCUSSION

56
57
58
59
60

1
2
3 **Physicochemical characterization of NPs in biological milieu.** For many particle-serum
4 systems the strongly bound hard corona is sufficiently stable so that it is possible to connect the
5 surface expression of surface adsorbed protein epitopes to the cell biological interactions.³² Thus
6 we first expose 100 nm SiO₂ NPs to different percentage of human serum (*i.e.*, 10%, 30%, and
7 50%), and isolate the hard corona-NP complexes by centrifugation. Using denaturalized
8 polyacrylamide gel electrophoresis (SDS-PAGE) and mass spectrometry, the irreversibly bound
9 hard corona proteins on SiO₂ NPs were separated, identified, and analysed (Figure 1a-b and
10 Table S1). Lipoproteins and immunoglobulins were found abundant in all coronas with over 10%
11 and 20% of the total corona proteins, respectively. Key examples include LDL and IgG. LDL
12 particles (20 - 30 nm in diameter), containing several thousand of cholesterol, phospholipid, and
13 triglyceride molecules, possess a single copy of ApoB-100, by which interacts with the LDLR.³³⁻
14
15 ³⁵ IgG, the most abundant type of antibody in the circulation, is consist of four peptide chains.
16
17 *Via* the Fc region, IgG binds to a family of Fc-gamma receptors (including FcγRI) to mediate
18 various immunological responses (*e.g.*, activation of phagocytes and antibody-dependent cell
19 mediated cytotoxicity).³⁶ It is unclear if the higher amount of IgG is a consequence of non-
20 specific adsorption or secondary recognition of disrupted corona proteins by blood borne
21 antibodies.

Next, we sought to characterise their physicochemical properties in appropriate biological milieu. In general for nanomaterials, the role of the milieu is critical and cell origin must be matched to the appropriate biological fluid to ensure fidelity of protein recognition.²⁹ For the following studies, we intend to use LDL as an example to illustrate the concept. Firstly, we re-dispersed the corona-NP complexes in serum depleted of the lipoproteins (lipoprotein depletion in Figure S1), as it is important to examine the particle uptake in milieu in the absence of free

1
2
3 LDL to avoid competitive binding. Subsequently, we characterised the same NP-corona
4
5 dispersions that used for cell uptake studies with varied serum concentrations and incubation
6
7 time. Time-resolved differential centrifuge sedimentation (DCS) analyses showed that in 10%
8
9 delipidised serum there is a degree of instability of the dispersion over some hours, but for both
10
11 30% and 50% serum concentrations the dispersions are stable over the lifetime of typical cell
12
13 uptake experiments (Figure 1c).
14
15

16
17 For such stable well-defined dispersions we can analyse the epitopes presented at the surface
18
19 of nanoparticle-corona complexes using immuno-labelling approaches that have the sensitivity to
20
21 detect 2-4 epitopes per nanoparticle.³⁷ monoclonal antibody (mAb) that recognises the region of
22
23 AA 97-526 of ApoB-100, close to the LDLR recognition site, was conjugated to a gold NP (4.5
24
25 nm, Figure S2 a-b) or a QD (4 nm, Figure S2 c-d), respectively. After incubation with immuno-
26
27 gold NP-mAbs, the ApoB-100 epitopes were visualized by transmission electron microscopy
28
29 (TEM) (Figure 2a and b). To quantitatively detect the epitope presentation in the same conditions
30
31 as the NPs are exposed to the cells, we employed QD-mAb mapping technique.³⁸ Firstly, we
32
33 examined the titration of ApoB-100 epitopes on the coronas formed by exposure of NPs to 10%,
34
35 30%, and 50% human serum at 37 °C for 1 h and re-dispersed in PBS. Different numbers of
36
37 ApoB-100 epitopes were detected on the different coronas, with the 10% serum corona showing
38
39 the highest number of ApoB-100 epitopes (Figure 2c). Subsequently, we performed the titration
40
41 curve of QD-mAb probes with the corona-NP complexes that were formed in 50% serum and
42
43 then re-dispersed in 50% delipidised serum for 1, 4, and 7 h. The three titration-curves showed
44
45 significant overlapping, suggesting the number of epitopes remains relatively constant
46
47 throughout the time period (Figure 2d). It is noted that the number of ApoB-100 epitopes reached
48
49 a plateau of 60 with an increase ratio of the QD-mAb probes to SiO₂ NPs (Figure 2d), which is
50
51
52
53
54
55
56
57
58
59
60

1
2
3 similar to the number of ApoB-100 epitopes that was quantified for the same hard corona (*i.e.*,
4 50% serum corona) re-dispersed in PBS for 1 h (Figure 2c). This further supports the notion that
5
6 the corona-NP complexes are stable. Taken together, Figure 2 establishes that potential
7
8 recognition fragment of ApoB-100 is indeed extensively presented at the NP surface in
9
10 biological milieu. The question is if it is still recognizable by the relevant receptor, LDLR.
11
12
13
14

15 **Target cells for study of NP-receptor interactions.** A straightforward way of detecting
16
17 specific uptake pathways is to compare the NP uptake kinetics curves (for example using time-
18
19 resolved flow cytometry) of two identical populations of cells, one of which has many less (or
20
21 more) receptors of a given type than the other population of cells with other key receptors that
22
23 can interact with the NPs remaining unchanged.³⁹ Silencing RNA (siRNA) of the receptors of
24
25 interest could be used to determine recognition of NPs by decreasing the receptor expression. To
26
27 explore the siRNA approach, we transfected LDLR siRNA to decrease the endogenous
28
29 expression of LDLR in A549 human lung epithelial cells (Figure S3). By comparison of particle
30
31 uptake between LDLR siRNA and scrambled siRNA transfected A549 cells, it has confirmed
32
33 that LDLR down regulation leads to a decrease of NP uptake (Figure S4). It is worth noting that
34
35 LDL exists in different forms in serum (*e.g.*, oxidized LDL), and besides LDLR it can be
36
37 recognised by other receptors, including LOX-1, CD36, and Toll-like receptor 4 (TLR-4).^{40,41} A
38
39 closer analysis has shown that transfection with LDLR siRNA in A549 cells concurrently
40
41 increased LOX-1 expression (Figure S3), suggesting a high degree of co-regulation of the genes.
42
43 Given the cross talking between the receptors, it suggests that comparison of reference and
44
45 silenced cells may not be a reliable approach in this case.
46
47
48
49
50
51
52

53 Alternatively, in this study we have developed a receptor-tag fusion protein expression system
54
55 that can 'host' a range of target receptors in HEK-293T cells (Figure 3). These cells have a very
56
57
58
59
60

1
2
3 low endogenous expression level of LDLR, and transfection of LDLR does not appear to co-
4 regulate at gene (or protein) level within the relevant receptor clusters (Figure S5). Crucially, the
5 receptor is fused with HaloTag®, which can then be labelled with a fluorescent HaloTag®
6 ligand, TMR (Figure 3a). This dye labelling serves an intrinsic measure of receptor expression
7 on a cell-by-cell basis using flow cytometry. As it was shown in Figure 3b-c, the expression of
8 LDLR-HaloTag® fusion protein and HaloTag® protein alone varied significantly between cells.
9
10 Some cells failed to be transfected (the left-most low TMR subpopulation in Figure 3b and c)
11 even with optimisation of the transfection (Figure S6). Hence, we note that if the complete
12 ensemble of cells after transfection is used (both parts of the populations in Figure 3b) it
13 becomes difficult to identify NP-receptor recognition. The correlation between receptor
14 expression level and NP uptake is critical for confirming the specific corona epitope-receptor
15 recognition, given the heterogeneity in both receptor expression and particle-surface
16 presentation. Thus, cell subpopulations (*i.e.*, high TMR and low TMR) were sorted based on
17 TMR intensity. Western blot (Figure 3d) and RT-qPCR (Figure 3e) both confirm that TMR
18 levels can be used as a proxy for receptor expression.
19
20
21
22
23
24
25
26
27
28
29
30
31
32
33
34
35
36
37

38 To confirm functionality of the expressed LDLR, we examined the uptake of fluorescently
39 labelled LDL in the high TMR subpopulations (*i.e.*, transfected cells). A four-fold increase in the
40 fluorescence of cells transfected with LDLR was observed compared with the empty vector
41 transfected cells (Figure 3f). It is noted that the LDL uptake was independent of LDLR
42 expression level in the high TMR subpopulation (Figure 3g), suggesting that average numbers of
43 expressed plasma membrane receptors are high and functional.
44
45
46
47
48
49
50
51
52

53 ***In situ* interactions of NPs with LDLR.** Using the above-mentioned LDLR-tag fusion protein
54 expression system, we examined the cell membrane adhesion and uptake of NP-corona in
55
56
57
58
59
60

1
2
3 delipidised serum. For the membrane adhesion experiment, the cells were incubated with NP-
4 corona complexes at 4 °C for 1 and 4 h followed by extensive washes to remove unbound NPs,
5
6 and subsequently chased in NP-free media at 37 °C for 30 min. For the uptake experiment, the
7
8 cells were continuously incubated with NP-corona complexes at 37 °C for various time intervals.
9
10 As shown in Figure 4, significantly increased membrane adhesion and uptake by LDLR-
11 transfected cells (*i.e.*, the high TMR subpopulation) was observed in all dispersions in
12
13 comparison to cells transfected with empty vector. It is also noted that at higher NP
14
15 concentration (1mg mL⁻¹) and a higher serum concentration (50% delipidised serum), the
16
17 specific uptake of NPs by LDLR was maximized, as the baseline uptake (*i.e.*, uptake in cells
18
19 transfected with empty vector) was minimized due to other uptake pathways suppressed by
20
21 serum competition (Figure 4 c-d). Under such conditions, the scatter plot (4 h time point as an
22
23 example) showed a high correlation between LDLR expression and NP uptake on a cell-by-cell
24
25 basis in the transfected cells (highlighted in the inset box of Figure 4e).
26
27
28
29
30
31
32
33

34 To further establish the specificity of the ApoB-100 interaction we carried out competition
35 uptake experiments (50% delipidised serum, 4 h) for conditions identical to Figure 4c and d, but
36
37 in the presence of increasing concentrations of fluorescently labelled LDL (Figure 5). Then we
38
39 can simultaneously measure the uptake of NPs and LDL and find that at around 16 nM LDL here
40
41 is quite a sharp accumulated displacement-type transition in which predominantly NP uptake
42
43 crosses over to predominantly LDL uptake (Figure 5a-c). The scatter plot of LDL and NP
44
45 fluorescence intensity indicates that cells that interact most strongly with LDL also have the
46
47 highest NP uptake, suggesting involvement of the same receptor (Figure 5d). Confocal
48
49 microscopy images have also shown a progressive competitive uptake NPs with an increase of
50
51 free LDL (Figure 5e-g).
52
53
54
55
56
57
58
59
60

1
2
3 We remark that the specific recognition of serum corona by LDLR can be reproduced from
4 independent experiments using the SiO₂ NPs made in house and commercially sourced with the
5 same surface and similar size (Figure S7). Collectively these observations set a high standard of
6 reproducibility, which we find to be broadly applicable to a number of other particle and receptor
7 systems.
8
9

10
11
12
13
14
15 **Concurrent interactions of NPs with FcγRI receptor.** To provide a different perspective, we
16 present (in less detail) analogous data for FcγRI, a receptor that recognises the Fc regions of
17 IgGs, and a member of the important receptor superfamily that promote phagocytosis of (for
18 example) opsonized particles and infectious agents.^{42,43} The presentation of Fc epitopes in the
19 biomolecular corona was quantified by using anti-IgG (Fc) QDs labelling. It was shown around
20 180 Fc epitopes were detected in the corona (Figure 6b), which is higher than the ApoB-100
21 epitopes (around 60 epitopes) and is consistent with more abundant immunoglobulins found in
22 the corona than apolipoproteins (Figure 1b).
23
24
25
26
27
28
29
30
31
32

33
34 Next, we employed the receptor-tag fusion expression system to examine the specific
35 recognition by FcγRI receptor. As shown in Figure 6c and d, FcγRI-transfected cells exhibited
36 increased uptake of particles compared to untransfected cells in both 30% and 50% IgG-depleted
37 serum, suggesting FcγRI plays a role in particle recognition. The overall uptake scale in IgG-
38 depleted serum is much smaller than that in LDL-depleted serum, despite the fact that abundance
39 of IgG and LDL in the corona and the affinity of free IgG and LDL to FcγRI and LDLR,
40 respectively, are comparable. Also uptake using dual depleted serum (*i.e.* lipid- and IgG-
41 depleted) shows little difference between FcγRI-transfected and control cells (Figure S8)
42 possibly suggesting a much larger interaction between particles and LDLR.⁴⁴ The reasons for the
43 apparently less effective interaction of IgG are not clear, and we do not believe it prudent to
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 over-interpret this observation. We do note, however, that the typical affinities of recognition
4 sites on NPs may be quite unrelated to that of the native protein, and could also vary significantly
5
6 on a particle-by-particle basis. Such questions go far beyond the current studies, and may require
7
8 additional tools.
9
10

11 12 13 14 15 CONCLUSIONS

16
17 Fundamentally, the size of NPs moves them into the range where many intrinsic biological
18 messages are passed and processed. Since adsorption of biomolecules on the NPs ‘labels’ them
19 with endogenous molecules, this potentially allows for ubiquitous ‘accidental’ involvement in
20 biological processing. Thus, NPs may be ‘mistaken’ for endogenous (*e.g.*, lipoproteins) or
21 commonly occurring exogenous objects (*e.g.*, viruses), potentially manifested in the nature of
22 their clearance and other outcomes. In this study, by using LDL and IgG as examples we have
23 demonstrated that adsorbed proteins on SiO₂ NPs can present functional epitopes to allow the
24 specific recognition of receptors. While this study has been focused on two types of receptors,
25 we have been able to express a wide spectrum of receptors using such a system (*e.g.*, scavenger
26 receptor class A member 1, scavenger receptor class B member 1, stabilin-1, stabilin-2, and other
27 ten receptors that are abundant in the liver), and consider the platform will be of broad
28 significance for NP-receptor recognition studies.
29
30

31
32 It would also be important to note that these are only the first steps. There are still several
33 significant limitations that are a consequence of the complexity of NP-cell interactions. For
34 example, NP-protein complexes are highly heterogeneous system in which we have recognized
35 major contributions from predominant, not rare, NP subpopulations. In addition, multivalent
36 interactions between receptors and NPs have often been speculated upon, but the synergies

18 METHODS

19
20 **Materials:** Fluorescein isothiocyanate (FITC)-labeled 100 nm SiO₂ NPs with plain surface
21 were synthesized at the CBNI as described previously.⁴⁵ 100 nm green fluorescent, plain surface
22 SiO₂ NPs (PSi-G0.1) were purchased from KISKER-BIOTECH (see characterization in Figure
23 S9). Anti-LDL Receptor antibody [1B10H10] (ab204941), Anti-FcγRI antibody [3D3]
24 (ab140779), and Anti-Mouse IgG H&L (HRP) (ab6728) were purchased from Abcam. Anti-
25 ApoB-100 sc-13538, Anti-ApoA-I sc-13549, and Anti-ApoE sc-13521 were purchased from
26 Santacruz Biotech. CD64/FCGR1A Antibody (10.1) MA1-10270 and Goat anti-Mouse IgG
27 (H+L) Secondary Antibody, and Alexa Fluor® 488 conjugate (A11029) were ordered from
28 Thermo Fisher. Human serum (HS) was purchased from BIOCHROM. Delipidised human serum
29 was purchased from SERALAB. IgG-depleted human serum was purchased from INNOV-
30 RESEARCH. The plasmid vectors for expression of LDLR (FHC01394) and FcγRI (FHC03501)
31 were purchased from KAZUSA DNA Research Institute. Quantum™ Simply Cellular® anti-
32 Mouse IgG (BLI815B-5) was ordered from Bangs lab. Propan-2-ol (P/7507/5) was purchased
33 from Fisher Chemical. LDLR Silencer® Select siRNA (s224006), Silencer® Select Negative
34 Control No.1 (439064), and Oligofectamine transfection reagent (12252011) were purchased
35 from Thermo Fisher. Skimmed milk powder (70166), Sodium dodecyl sulfate (L3771), Glycine

19 (07964)) were purchased from Sigma Aldrich and used as received. Color Plus Pre-stained
20
21 Protein Ladder, Broad Range (10-230 kDa) (P7711S) and Blue Loading Buffer for SDS-PAGE
22
23 were purchased from New England Bio-Labs (cat. no. B77035). PVC calibration standard for
24
25 DCS measurements 483 nm (PS000483) was ordered from Analytik Ltd. BCA Protein Assay Kit
26
27 (23227) and RIPA buffer (89901) were ordered from Thermo Scientific. Propan-2-ol (P/7507/5)
28
29 was purchased from Fisher Chemical. Tellurium, 99.8%, Powder (315990250) was purchased
30
31 from Acros Organics.

32
33
34 **NP characterisation:** SiO₂ NPs used in this study were characterized by dynamic light
35
36 scattering (DLS) and DCS to ensure the stability of the dispersion (Figure S9). To obtain hard
37
38 corona, 1 mg of 100 nm SiO₂ NPs were incubated with 1 mL of 10% human serum (5 mg mL⁻¹
39
40 protein concentration) or 30% human serum (15 mg mL⁻¹ protein concentration) or 50% human
41
42 serum (25 mg mL⁻¹ protein concentration) at 37 °C for 1 h on a shaker followed by
43
44 centrifugation. 1 mg mL⁻¹ of 100 nm SiO₂ NPs were incubated with to allow equilibrium to be
45
46 reached. Then the samples were centrifuged for 20 min at 16,000 rcf. After centrifugation the
47
48 pellet was re-dispersed and washes with phosphate-buffered saline (PBS, pH 7.4) for three times.

3 The protein corona was analysed by SDS-PAGE and electrospray liquid chromatography mass
4 spectrometry (LC-MS/MS) following the protocol described previously.³ The corona-NP
5 complexes were re-dispersed in 10%, 30% or 50% delipidised human serum, and were
6 characterized by DCS at different time points before the epitope mapping analysis. The NP
7 dispersions were characterized by DCS using a CPS Disc Centrifuge DC24000. DCS
8 measurements were done using a CPS Disc Centrifuge DC24000. For SiO₂ NPs a 8-24% sucrose
9 density gradient (suitable for the nanoparticle density range used) prepared in relevant solvents
10 (PBS, pH 7.4) was used with a disk speed of 20,000 rpm. The particles were measured between
11 0.001 and 1 μm, each measurement being calibrated with PVC standard of nominal size 483 nm
12 (Analytic Ltd.).

26

27 **Epitope mapping:** The synthesis of small gold NPs (5 nm) was performed following the
28 procedure reported previously.⁴⁶ In order to functionalized the gold NPs with antibodies, the
29 citrate of the NP surface was exchanged by a O-(2-Carboxyethyl)-O'-(2-mercaptoethyl)
30 heptaethylene glycol (SH-PEG (7)-COOH, MW= 458.56 g/mol). Briefly, 50 mL of gold NPs
31 after synthesis were incubated overnight, under continuous stirring, with SDS (0.03%), NaOH
32 (25 mM) and an equivalent amount of SH-PEG (7)-COOH to obtain 5,000 chains per NP. The
33 carboxylated gold NPs were washed three times and concentrated with centrifugal filter units
34 (10,000 MWCO). The gold NPs were characterized by DCS and EM. The synthesis of
35 mercaptopropionic acid protected CdTe QDs was performed following the procedure reported by
36 S. Penades *et al.*⁴⁷ The QDs were purified by precipitation with acetone. Finally the QDs were
37 separated by centrifugation and dialyzed 48 h against PBS buffer. The QDs particles are
38 characterized by DCS and fluorescence spectroscopy.

2
3 The CdTe-MPA QDs and gold NPs were functionalized with antibodies: 1 mL of NP
4 suspension (3.3 nmol) was mixed with 0.4 mg of EDC and 0.8 mg of Sulfo-NHS in PBS buffer
5 pH 7.4, and the mixture was incubated at 37 °C for 30 min. The activated NP solution was
6 applied to a PD-10 column using 10 mM PBS pH 7.4 as the exchange buffer. Then 0.6 nmol of
7 IgG antibody was added to 1 nmol of NPs and the mixture was stirred at 37 °C for 1 h.
8 Subsequently, the activated carboxylic groups were blocked with 5 mg of 4-Aminophenyl β -D-
9 galactopyranoside, and the mixture was incubated overnight in a final volume of 1.5 mL. NPs
10 conjugated with antibodies (650 nM) were stored at 4 °C.
11
12

13
14
15 For the immuno-gold labelling, mAb-gold NPs (5 nm) in excess were adding to a given
16 number of corona-NP complexes. After the incubation, the NPs were collected by centrifugation
17 at 16,000 rcf and washes with PBS and milliQ water for 5 times each to remove unbound mAb-
18 gold NPs. And then the samples were prepared for TEM as described previously.³⁰ A number of
19 300 SiO₂ NPs were analysed for immuno-gold labelling counting by FEI Tecnai G2 20 Twin
20 TEM operating at accelerating voltage of 200 kV. For the QD-mAbs labelling, different
21 amounts of immuno-QDs in PBS (up to final conc. at 500 nM) were added to the NP-corona
22 complexes (final conc. at 1 mg mL⁻¹) under constant agitation for 1 h at 37 °C. Subsequently, the
23 samples were centrifuged at 16,000 rcf and re-dispersed in fresh PBS twice to remove the
24 unbound QD-mAbs. The interaction between the immuno-QDs and the corona was studying by
25 steady-state fluorescence spectroscopy as described previously.³¹

1
2
3 and passaged three times a week, as they approached 70 - 80% surface coverage. The cells have
4
5 been routinely tested as mycoplasma contamination free by using MycoAlert Assay kit
6
7 (Cambrex Bio Science, Nottingham, UK).
8
9

10 **RNA extraction and RT-qPCR:** RNA was extracted using InviTrap®Spin Cell RNA Mini
11
12 Kit from Stratec (0711). The amount of RNA was quantified by NanoDrop and the cDNA was
13
14 obtained by reverse transcription. Quantitative PCR was performed with the cDNA of each
15
16 population of interest and the specific primers for each receptor. Comparative CT method
17
18 ($\Delta\Delta CT$) was used to perform the calculations. The CT (Cycle Treshold) of the receptor of
19
20 interest was normalized with the CT of the β -actin to obtain its ΔCT . The values of ΔCT of the
21
22 receptors were further normalized with the ΔCT of the control cells (*i.e.*, untransfected cells), the
23
24 result of which generated the final data set ($\Delta\Delta CT$).
25
26
27
28

29 **Western blot:** Proteins separated by SDS-PAGE were transferred to a PVDF membrane using
30
31 Mini-PROTEAN Tetra Trans-Blot Module under a constant voltage of 100 V for 1 h.
32
33 Membranes were then incubated at RT for 1 h in blocking solution of 5% skimmed milk in TBS-
34
35 TWEEN (150 mM NaCl, 10 mM Tris-HCl, 0.1 % Tween, pH 7.5). Afterwards, the membrane
36
37 was incubated overnight at 4 °C with the antibodies of interest in blocking solution and wash for
38
39 1 h in TBS-TWEEN. The blot was incubated at RT for 1 h with 1:2000 of Anti-Goat HRP in
40
41 blocking solution and washed for 1 h in TBS-TWEEN. The membrane was incubated for 1 min
42
43 in ECL Western Blotting Substrate mix and visualized in Syngene G: BOX imaging system.
44
45
46
47

48 **Silencing of LDLR expression in A549 cells:** 17,000 cells were seeded in 24-well plates
49
50 (Greiner), and incubated for 24 h before silencing of LDLR. Cells were then transfected with
51
52 LDLR siRNA or scrambled siRNA using Oligofectamine reagent according to the
53
54 manufacturer's instructions, and incubated for 72 h.
55
56
57
58
59
60

1
2
3 **Transfection of HEK-293T cells:** HEK-293T cells were plated 24 h before transfection at a
4 density of 104,000 cells in each well into a 12-well plate (Cellstar® Greiner bio-one) in 1 mL of
5 completed medium DMEM Glutamax (GIBCO) supplemented with 10% FBS. After 24 h cells
6 were transfected using FuGENE® 6 (Promega)-to-DNA ratio of 3.5:1 for LDLR and 3:1 for
7 FcγRI. Plasmid DNA (0.02 μg μL⁻¹) was added to a sterile tube containing Opti-MEM medium
8 (GIBCO). FuGENE® 6 reagent was added to the solution and mixed carefully by pipetting for
9 15 times. The solution was incubated at RT for 10 min. 50 μl was then gently added drop wise
10 onto each well and incubated for 24 h at 37 °C and 5% CO₂.
11
12
13
14
15
16
17
18
19
20
21

22 **Cellular uptake of NPs:** To expose the cells to the NPs, after 24 h of the transfection, cells
23 were washed for at least 30 min in serum-free DMEM. The medium was then replaced by the
24 freshly prepared NP dispersions. Experiments were performed by exposing the cells to the NP
25 dispersions at 0.1 mg mL⁻¹ or 1 mg mL⁻¹ at 37 °C and 5% CO₂ for 1, 4, and 7 h. Cells then were
26 washed with 1 mL per well of completed DMEM Glutamax supplemented with 10% FBS. One
27 fifth of the volume was replaced with TMR HaloTag® ligand at a concentration of 200 nM in
28 completed DMEM Glutamax, and incubated at 37 °C, 5% CO₂ for 15 min. The cells were
29 washed with completed DMEM Glutamax once and PBS twice, and harvested after
30 trypsinization. Cell pellets were re-dispersed in completed DMEM Glutamax and placed on ice.
31 Cell fluorescence intensity was measured using a CyAn ADP (BECKMAN COULTER Flow
32 Cytometers). Results are reported as the median of cell fluorescence intensity of transfected cells
33 (high TMR subpopulation). At least 15,000 cells were analyzed in each sample.
