The specific immobilisation of a histidine tagged protein, Spi, onto mono-anchored nickel(II) cyclam functionalised SBA-15 is reported.

Enzymes have the capacity to catalyse reactions with high regio- and chemoselectivity while operating under mild conditions, properties which have led to a surge in the use of biocatalysts. However, the application of biocatalysts in many industrial applications is restricted as the process of removing the enzyme from the reaction mixture can cause denaturation of the biocatalyst. Immobilized enzymes can display activities superior to that of the free enzyme while remaining stable and exhibiting significant catalytic activity in harsh media such as non-aqueous solvents. However, more often than not immobilized enzymes display activities significantly less than free enzyme. Mesoporous silicates (MPS) have been extensively studied as supports for enzymes. Some of the properties which make MPS attractive as solid supports include narrow pore size distributions, large surface areas (up to 1500 m$^2$/g), chemical and thermal stability, the ability to chemically functionalise the surface, and pore dimensions capable of accommodating enzymes. While a wide range of proteins have been immobilised on to MPS in many cases the immobilised enzyme displays reduced activity in comparison to the free enzyme and can not be efficiently recycled due to leaching of the enzyme from the support.

Mesoporous organic-inorganic hybrid materials possess co-ordination binding sites and hydrophobic/hydrophilic binding patches. Among the possibilities offered by this class of solids is the ability to strongly chelate metal cations which can remain chemically accessible. Previous reports of silicates functionalised with cationic metals have been used for electroconductive, biocatalytic, and optical applications. Tailoring the surface of a mesoporous silicate and the surface of a protein can enable specific anchoring of the protein. This can negate consideration of the many variables involved when immobilising a protein onto MPS. The approach taken here utilises a technique in widespread use in recombinant protein purification; immobilised metal affinity chromatography (IMAC). Adsorption of histidine-tagged proteins on to Ni or Co functionalised surfaces has been demonstrated previously. Here we present a method for the generation of a supported biocatalyst in which SBA-15 is functionalised with Ni$^{2+}$ and used as a host material for the specific adsorption of a model protein, His$_6$-tagged Spi.

SBA-15 is a mesoporous silicate generated from a non-ionic surfactant template and displays a hexagonally ordered array of mesopores with microporous interconnections, resulting in a unique 3-D micro-mesoporous network. Cyclam (1,4,8,11-tetraazacyclotetradecane) can bind to a range of transition metals, including nickel. Ni-cyclam complexes have been extensively studied, in particular the tetra-N-substituted complexes. Cyclam which is mono-tethered to the surface of SBA-15 displays a greater degree of metal uptake than di- or tetra-tethered cyclams. In this study, a mono-N-substituted Ni-cyclam complex was attached to the surface of a mesoporous silicate in a stepwise manner (Scheme 1). The protein used as a model system, Spi, is a small protease inhibitor from the human pathogen Streptococcus pyogenes. The His$_6$-tagged form was chosen due to its small size (14.7 kDa) and favorable pI (5.4). Spi does not possess a high surface charge, ensuring that electrostatic interactions with the carrier will be minimised.

SBA-15-Ni-cyclam was prepared from SBA-15 with a pore diameter of 8.5 nm. SBA-15 was functionalised with 3-iodo-trimethoxypropylsilane to provide an iodo-functionality which increased the iodo functionality on the silicate surface. The iodo-functionality was required for the attachment of a His$_6$-tagged protein to nickel cyclam. This green colour faded as the iodo functionality was removed and attachment of the cyclam occurred, yielding a white powder once again. Upon complexation of nickel with the cyclam ring the final material remained a pale yellow colour indicating that nickel cyclam had been formed. SBA-15 showed a pore diameter of 8.5 nm, estimated from condensation relative pressure, and a BET surface area of 742 m$^2$/g (Table 1). Low-angle XRD analysis displayed a very
intense diffraction peak and two weaker peaks, assigned to the 100, 110 and 200 planes respectively, which are characteristic of the material. The procedure required for the surface functionalisation of the silicate had a notable effect on the original substrate structure, in particular the surface area, pore volume and pore diameter. This was evident from the reduced N$_2$ adsorption capacity after functionalisation. SBA-15-Ni-cyclam displayed a greater than 80% reduction in surface area (138 m$^2$/g) and a pore diameter of 5.5 nm. XPS analysis of SBA-15-cyclam confirmed the presence of nitrogen with a binding energy consistent with carbon binding. The presence of residual unreacted iodine in an alkyl environment was also detected in this sample. Analysis of SBA-15-Ni-cyclam displayed a similar spectrum to SBA-15-cyclam, with the addition of a peak corresponding to nickel in a nitrogen-organic environment. While TEM images of SBA-15-Ni-cyclam (Figure 1) display the hexagonal structure of the parent SBA-15 material, XRD analysis of SBA-15-Ni-cyclam displayed a loss of diffraction peaks for the 110 and 200 planes as well as the prominent 100 plane. This data is consistent with reduced scattering contrast between the silica wall and the pore network due to functionalisation as well as a possible partial collapse of the pore wall structure. To determine whether the change in N$_2$ adsorption capacity was due to the reaction conditions or the metal functionalisation, SBA-15 was exposed to the functionalisation conditions without reagents. N$_2$ adsorption analysis displayed a smaller reduction in BET surface area (368 m$^2$/g) and an increase in pore diameter (9.4 nm) indicating that the changes in pore diameter and surface area of SBA-15-Ni-cyclam are a consequence of the incorporation of the large organic macrocycle into the pore channel coupled with a partial collapse of the pore structure. Elemental analysis of SBA-15-cyclam showed no presence of nickel as expected whereas SBA-15-Ni-cyclam contained 1.18% w/w nickel (201 µmole g$^{-1}$). SBA-15-Ni-cyclam had a N/ Ni molar ratio of 6:1, close to the 4:1 ratio expected for complete nickel-cyclam coordination. A nickel/protein excess ensures availability of the metal for protein binding as well as compensating for the presence of micropores in the SBA-15 scaffold, which are inaccessible to the protein. Thermal gravimetric analysis of SBA-15, SBA-15-cyclam and SBA-15-Ni-cyclam, displayed a sharp weight loss at 50°C, corresponding to the evaporation of physisorbed water. Above 50°C, the as-synthesised SBA-15 did not display any further significant reduction in weight, as expected. However, SBA-15-cyclam and SBA-15-Ni-cyclam both display weight losses from 300 – 400 °C with SBA-15-Ni-cyclam displaying a markedly greater loss than SBA-15-cyclam (29 and 17% respectively). These weight losses can be attributed to the loss of Ni-cyclam and cyclam, respectively.

non-specific binding of His6-Spi to unfunctionalised SBA-15. After pre-incubation of His6-Spi in 2% PEG400, SBA-15-Ni-cyclam displayed a protein uptake of 2.73 µmole g⁻¹ (79% of protein), whereas the unfunctionalised SBA-15 displayed a protein uptake of only 0.13 µmole g⁻¹ (4%). Specific binding of His6-Spi to SBA-15-Ni-cyclam in the presence of PEG is lower due to the lower initial concentration of protein (17.4 vs. 39.3 µM). Leaching studies of His6-Spi immobilised onto SBA-15-Ni-cyclam displayed no desorption of the protein. To further confirm the specific nature of the interaction of the histidine tag and the Ni(II) cyclam complex, SBA-15 and SBA-15-Ni-cyclam were exposed to Spi from which the His6-tag had been removed by proteolysis. SBA-15 displayed no protein uptake and SBA-15-Ni-cyclam displayed a negligible protein uptake of only 0.13 µmole g⁻¹ (4%). This result provides strong evidence that the interaction between His6-Spi and SBA-15-Ni-cyclam is in the presence of 2% PEG400 is as a result of coordination of the Ni²⁺ by the imidazole rings of the His6-tag.

As protein uptake occurred primarily on the nickel functionalised material, we conclude that adsorption occurred through the His6-tag on available nickel sites. These results open up the possibility of immobilising any His6-tagged protein/enzyme for use as a stable and reusable biocatalyst as well as obviating the necessity of an often laborious search for ideal immobilisation conditions for specific proteins/enzymes.
